Coding Standard

Goals

Efficiently develop code and applications with the following qualities:

- Robust: runs without crash and protects the data from being lost or corrupted.
- **Secure**: protects the data from being stolen or hacked.
- **Ergonomic**: can be used in an productive and intuitive manner.
- **Efficient**: minimizes processing times to maximize the user productivity.
- Maintainable: is easy to fix and enhance by any programmer in the team.
- **Extensible**: is easy to extend with new features by reusing existing components.
- Consistent: looks like it has been designed and implemented by a single developer.

Specificity

This coding standard favors readability over compactness, by:

- Forbidding the use of cryptic acronyms, abbreviations, prefixes and suffixes;
- Using different letter cases for classes, class members and local variables;
- Including the class name in the attribute and variable names.

Rules

- Develop the application and its components with simple, robust and efficient code which will be easy to understand, extend and debug by any programmer in the team.
- Develop any piece of code so that it's:
 - easy to understand just by itself;
 - o impossible to guess who has actually worked on it.
- Use **American English** for all the code, including comments.

```
InitializeColor();
MoveForward();
```

- Use the **meter** as the default distance unit.
- Use the **second** as the default time unit.
- Use **four spaces** instead of tabulations.
- Choose **short meaningful identifiers** for class, attribute, method, constant and variable names.
- Use standard prefixes:
 - o First, Last, Post
 - o Prior, Next
 - Sub, Super, Base
 - o Initial, Final

- o Old, New
- o Backward, Forward
- o Left, Right
- o Back, Front
- o Bottom, Top
- o Minimum, Maximum
- o Lower, Higher, Upper
- o Horizontal, Vertical

• Use standard suffixes:

- o Index, Count
- o Array, List, Map, Dictionary

• Use standard verbs:

- o Initialize, Update, Finalize
- o Is, Has
- Reset, Set, Get, Find
- o Clear, Fill
- o Add, Remove
- o AddFirst, AddLast
- o Create, Destroy
- o Start, Stop
- o Begin, End
- o Enter, Exit
- o Open, Close
- o Read, Write
- o Load, Save
- o Pause, Resume
- o Enable, Disable
- o Lock, Unlock
- o Select, Deselect
- o Activate, Deactivate
- o Attach, Detach
- o Increment, Decrement
- o Increase, Decrease
- o Compress, Decompress
- o Connect, Disconnect
- o Send, Receive
- o Grant, Revoke
- Write **types** in **UPPER_CASE**, without articles.

```
class TANK_SHELL
{
}
```

• Write **type members** (methods, attributes, constants, etc) in **CamelCase**, without articles.

```
Tank.ShootShell();
```

• Write local variables and method parameters in snake_case, without articles.

```
player_name
```

• Don't use acronyms, abbreviations or single-letter variables.

```
TANK FindTank(
   int tank_identifier,
   int first_tank_index,
   int post_tank_index
{
   int
        tank_index;
    for ( tank index = first tank index;
         tank_index < post_tank_index; // no i, j, n, etc</pre>
         ++tank_index )
    {
        if ( TankArray[ tank index ].Identifier == tank identifier )
            return TankArray[ tank_index ];
        }
    }
    return null;
}
```

• If you really have to use an acronym, capitalize it in member names.

```
DATABASE_URL
DatabaseUrl;
```

• If a variable name collides with a predefined identifier, simply add a trailing underscore.

```
CLASS
    class_;

class_ = new CLASS;
```

• Include the class name (without numbers) in the attribute and variable names.

```
Dictionary<PLAYER, string>
    ActivePlayerDictionary;
List<ENEMY>
```

```
CloseEnemyList;
TANK[]
    EnemyTankArray;
VECTOR_3
    InitialShellPositionVector,
    TankVelocityVector;

void ShootShell(
    )
{
    SHELL
     last_shot_shell,
     shot_shell;
    ...
}
```

- Start method names by a verb in the imperative mood (Set, Get, Find, ...).
- Use a verb in the indicative mood for boolean inquiries (Is, Has, Can, ...).
- Declare the method parameters in the same order as in the method name.

```
bool FindPlayerIndexByName(
    ref int player_index,
    string player_name
    )
{
    ...
}
```

• Use a positive affirmation for boolean variables and attributes.

```
if ( game_is_paused )
{
    ...
}
```

• When the attribute name starts like its owner type, omit the common prefix.

```
class TANK
{
    TANK_SHELL[]
        ShellArray;
    bool
        IsDamaged;

    void ShootShell(
        TANK_SHELL tank_shell
        )
    {
```

```
····
}
}
```

• Align matching braces.

```
bool CanShoot(
    )
{
    return ShotShellCount < MaximumShellCount;
}

// ~~

void ShootShell(
    VECTOR_3 initial_velocity_vector
    )
{
    ...
}</pre>
```

• Use braces even for single statement blocks.

```
if ( remaining_shell_count > 0 )
{
    ShootShell();
}
else
{
    Reload();
}
```

• Declare each attribute, variable and method parameter name on separate line.

```
int
   tank_count,
   tank_index;
```

- Try to declare all local variables at the start of the method, to improve the algorithm readability.
- Group local variables of the same type, and sort the declarations by ascending types and names, so that the declaration of a variable can be located at a glance.

```
int
    shell_count,
    shell_index,
    tank_count,
    tank_index;
string
    player_name,
    target_name;
```

- Try to split statements on several lines if they become wider than 100 characters, so that it's easy to edit two code files side by side on a single monitor.
- When splitting an expression on several lines, start the next lines with an operator and align it with the start of its left operand (or else indent it by 4 spaces).

• Add exactly one space:

```
after ([],before ) ]after if while for ...
```

- Add exactly one empty line:
 - o after a standard comment;
 - o after the local variable declarations;
 - o between a closing brace and the next statement;
 - o between a return statement and the prior statement.
- Use standard file extensions.

```
C#:csC:c, hC++:cpp, hppJavascript:jsHTML:htmlCSS:css
```

- Declare one class per source code file.
- Use the class name in lowercase as file name.

```
tank_shell.cpp
tank_shell.hpp
```

• Use the class name in uppercase for Unity source code files.

```
TANK_SHELL.cs
```

- Group the class elements by category, declared in the same predefined order:
 - o Imports.
 - o Types.
 - o Constants.
 - o Attributes.
 - o Constructors.
 - o Destructor.
 - o Operators.
 - Inquiries: instance methods which can't change the instance attributes.
 - Operations : instance methods which can change the instance attributes.
 - Functions: static methods.
- In a class, declare the called methods before the calling methods, so that the class code can be understood by a single sequential read.
- Use public attributes and methods, unless you really need to declare some of them as private.
- Delimitate the code sections with standard comments.

```
// -- IMPORTS
...

// -- TYPES

class NAME
{
    // -- CONSTANTS
    ...

    // -- ATTRIBUTES
    ...

    // -- CONSTRUCTORS
    ...

    // -- DESTRUCTOR
    ...

// -- OPERATORS
```

```
...
// -- INQUIRIES
...
// -- OPERATIONS
...
// -- FUNCTIONS
...
}
```

- Don't use standard comments for empty sections.
- Align multiple lines comments with the surrounding statements, and write them as sentences.

```
/*
A long explanation which is so long that it will have to be be split on several lines.
*/
...
```

• Align single line comments with the surrounding statements, and write them as sentences.

```
// A short explanation on a single line.
...
```

• Put end of line comments exactly four spaces after the statement, and start them in lowercase.

```
DoSomethingWeird(); // a short explanation
```

- Instead of adding comments to explain the code intent, refactor it to:
 - o make it easy to understand without comments;
 - o improve its reusability.
- Begin C++ header files with #pragma once.

```
#pragma once

// -- IMPORTS

#include "tank.hpp"
#include "tank_shell.hpp"
...
```

• Name the unit test class by simply adding a _TEST suffix to the class name.

Advices

- Design before you program, to avoid loosing precious time in developing the wrong solution to the wrong problem.
- First find what is really needed, by taking a few minutes to write:
 - a short text explaining how to use the application, to optimize the application interface before implementing it;
 - a short text explaining what the application components will do, to optimize the application architecture before implementing them;
 - a short text or test code explaining to the other programmers how they will use the application components, to optimize their interface before implementing them.
